method. For example, if you know the true value is Pi, and the errata for the approximation of Pi that is used to estimate is 0.0009, then the error estimate is about 1-in-1000. Note that the error estimate is not the actual error of the estimation method.

In my opinion, the theoretical error of pi approximations is much larger than this error estimate due to the fact that the true value is not a rational number. A: It's been my experience that if you want a method to be within X "bits" of the true value of

$\sqrt{\pi}$, you need $\log_2(X)$ bits in your method. You do not necessarily need to have a method which is exactly $\sqrt{\pi}$ bits away, but "within a constant factor" or within an arbitrarily-chosen factor - i.e. $\sqrt{\pi}-k$ bits, for any

$k>0$. For example, for generating random numbers in the interval $(0,1)$, you might use a method which generates a $x \in (0,1)$ by computing y as $y = \exp\left(-\frac{2^n}{1+2^n}x\right)$, for any $n>0$, so that $x = \log_2(1-y)$. This

method generates numbers in $\mathcal{O}(\log n)$ bits. If you choose $n = \lceil \lg\left(\frac{1}{\sqrt{\pi}} + \epsilon\right) \rceil$, you get roughly $\sqrt{\pi}$ bits of randomness, where ϵ is any positive real number. For approximating the square root,

the error is dominated by the error of the error estimate. If your method has an error estimate of Δ , then the error will be of the order of $\frac{\Delta}{2^n}$, for some n , where 2^n is the error-estimate significance level, and this is the only
