Fully portable: File hashes can be very helpful when trying to determine whether a file has been changed in any way, and they also used by online malware scanners to provide users with quick results if a file has already been analyzed recently. PocketHash is a very small program that allows you to calculate hashes using drag and drop, as well as view the most recent VirusTotal scan log for executable files. It is portable and easy to use, but it would still benefit from some improvements. Generate file hashes instantly Since it does not need to be installed before use, PocketHash can be launched as soon as you have downloaded the executable file. To generate hash values, simply drop a file in the main window. At present, the application generates MD5, SHA1 and SHA256 hashes, and it also calculates the file's entropy. It would have been great if it offered support for additional algorithms. View recent VirusTotal scan logs for executable files When processing an EXE file, the application grabs the most recent scan result from VirusTotal and displays a summary in the bottom field. You can get an idea of how dangerous a file might be from the number of alerts that it triggered. It is worth noting, however, that scan logs are only grabbed for executable files. Also, if a file has not been scanned already, the program cannot upload it, so you will have to access VirusTotal and scan it manually. Handy utility that features a rudimentary UI As far as the user interface is concerned, there isn't too much to say. The application has a very simplistic design, with no buttons and just a few fields where data is displayed. Overall, PocketHash can definitely prove helpful, but it could use some enhancements. Aside from a modernized UI, we would like to be able to view VirusTotal scan logs for other types of files, and support for more hashing algorithms would also be welcome.

[Alcohol consumption and the vascular risk of young men]. We evaluated the relationship between alcohol consumption and the vascular risk of young men. In the last analysis we observed only a statistically significant inverse association between alcohol consumption and the total cholesterol/HDL-cholesterol (TC/HDL-cholesterol) ratio. This was calculated from the values of the most recent blood samples. A TC/HDL-cholesterol ratio of less than 3.2 was also associated with a decrease in the risk of mortality (relative risk
